# PROGRAMMING USING C

# WEEK 12 USER DEFINED FUNCTIONS – RECURSIVE FUNCTIONS

NAME:LIRESH N V

**CLASS: AIML B** 

REG NO: 241501100

A binary number is a combination of 1s and 0s. Its  $n^{th}$  least significant digit is the  $n^{th}$  digit starting from the right starting with 1. Given a decimal number, convert it to binary and determine the value of the the  $4^{th}$  least significant digit.

#### Example

number = 23

- Convert the decimal number 23 to binary number:  $23^{10} = 2^4 + 2^2 + 2^1 + 2^0 = (10111)_2$ .
- · The value of the 4<sup>th</sup> index from the right in the binary representation is 0.

# **Function Description**

Complete the function fourthBit in the editor below.

fourthBit has the following parameter(s):

int number: a decimal integer

Returns:

int: an integer 0 or 1 matching the 4th least significant digit in the binary representation of number.

#### Constraints

 $0 \le \text{number} < 2^{31}$ 

#### Input Format for Custom Testing

Input from stdin will be processed as follows and passed to the function.

The only line contains an integer, number.

#### Sample Case 0

```
STDIN Function
-----
32 → number = 32
Sample Output 0
0
Explanation 0
     Convert the decimal number 32 to binary number: 32_{10} = (100000)_2.
     The value of the 4th index from the right in the binary representation is 0.
Sample Case 1
Sample Input 1
STDIN Function
77 → number = 77
Sample Output 1
1
Explanation 1
     Convert the decimal number 77 to binary number: 77_{10} = (1001101)_2.
```

The value of the 4th index from the right in the binary representation is 1.

```
Answer: (penalty regime: 0 %)
```

# Reset answer

```
1 . /*
     * Complete the 'fourthBit' function below.
 2
 3
     * The function is expected to return an INTEGER.
     * The function accepts INTEGER number as parameter.
 5
   int fourthBit(int number)
 8
 9 , {
      int binary[32];
10
        int i=0;
11
        while(number>0){
12 +
            binary[i]=number%2;
13
14
            number/=2;
15
            i++;
16
17
       if(i)=4){
18 +
19
           return binary[3];
20
21
        else
22
        return 0;
23 }
```

	Test	Expected	Got	
<b>V</b>	<pre>printf("%d", fourthBit(32))</pre>	0	0	~
<b>V</b>	printf("%d", fourthBit(77))	1	1	~

Passed all tests! <

Determine the factors of a number (i.e., all positive integer values that evenly divide into a number) and then return the p<sup>th</sup> element of the list, sorted ascending. If there is no p<sup>th</sup> element, return 0.

#### Example

n = 20

p = 3

The factors of 20 in ascending order are  $\{1, 2, 4, 5, 10, 20\}$ . Using 1-based indexing, if p = 3, then 4 is returned. If p > 6, 0 would be returned.

## **Function Description**

Complete the function pthFactor in the editor below.

pthFactor has the following parameter(s):

int n: the integer whose factors are to be found

int p: the index of the factor to be returned

Returns:

int: the long integer value of the pth integer factor of n or, if there is no factor at that index, then 0 is returned

#### Constraints

 $1 \le n \le 10^{15}$ 

 $1 \le p \le 10^9$ 

Input Format for Custom Testing

Input from stdin will be processed as follows and passed to the function.

The second line contains an integer p, the 1-based index of the factor to return.

# Sample Case 0

# Sample Input 0

STDIN Function  $10 \rightarrow n = 10$   $3 \rightarrow p = 3$ 

# Sample Output 0

5

# Explanation 0

Factoring n = 10 results in {1, 2, 5, 10}. Return the  $p = 3^{rd}$  factor, 5, as the answer.

# Sample Case 1

# Sample Input 1

STDIN Function  $10 \rightarrow n = 10$   $5 \rightarrow p = 5$ 

# Sample Output 1

0

```
Answer: (penalty regime: 0 %)
```

# Reset answer

```
1 + /*
